Lead Model Data

To accurately model the foundational data required for generating a new Lead, the following Standard and Custom fields must be provisioned:

Standard Fields:

- **Name**
- **Address**:
  - Street
  - Postal Code
  - City
  - State
  - Country
- **Email**
- **Phone**
- **Status**

Custom Fields:

- **Language**: Single Picklist (English, German, French, Spanish).
- **Currency**: Single Picklist (EUR, GBP, USD ***TBC***)
- **Sales Org**: Picklist (Auto-populated based on the assigned Sales Organization of the User creating the Lead. Values TBC)
- **Sales District**: Picklist (Values TBC)
- **Account Type**: Picklist More details in the Account Type Section

Record Types & Lead Processes:

The system architecture incorporates two distinct Record Types: **Customer** and **Distributor**.

Each Record Type will be mapped to its dedicated Lead Process:

- **Customer:** WESAL_leadPcr_customerProspect
- **Distributor:** WESAL_leadPcr_distributorProspect

Status Lifecycle

Initially, both Lead Processes will share a unified status flow:

- **New:** The default status upon Lead creation.
- **Prospect Created:** The terminal status applied once the Lead is successfully converted into a Prospect Account.

Account Type

The **Account Type** picklist field will be configured with the following permissible values. To ensure data integrity and streamline the user experience, these values are strictly mapped as the default and exclusive options for their respective Record Types:

Label	API Name	Record Type Mapping	Configuration Constraints
Sold to	0001	Customer	Default & Exclusive Value
Dealer Simple	0002	Distributor	Default & Exclusive Value

Lead to Account Mapping Logic

The following mapping shall be implemented within the Salesforce **Lead Conversion Settings** or via a **Record-Triggered Flow** to handle complex conditional logic (such as Record Type and Status transitions).

Account Field Mapping Table

Account Field	Source Lead Field	Transformation / Mapping Logic
Account Name	Company	Standard conversion mapping.
Type	RecordType	If Lead RT is **Customer Prospect** → **Customer**. If Lead RT is **Distributor Prospect** → **Distributor**.
Status	*Hardcoded*	Set to **Prospect** upon creation. (Transitions to **Pending** after SAP submission).
Fiscal Street	`Street`	Direct mapping.
Fiscal Postal Code	`PostalCode`	Direct mapping.
Fiscal City	`City`	Direct mapping.
Fiscal Country	`Country`	Direct mapping.
Email	`Email`	Direct mapping.
Phone	`Phone`	Direct mapping.
Account Currency	`Currency`	Direct mapping.
Sales Organization	`Sales Organization`	Direct mapping.
Account Group	`RecordType`	If Lead RT is **Distributor Prospect** → **Dealer Simple**. If Lead RT is **Customer Prospect** → **Sold To**.
Sales District	`Sales District`	Direct mapping.
Language	`Language`	Direct mapping.

Implementation Strategy: Beyond Standard Mapping

While standard Salesforce Lead Mapping covers basic fields, the conditional logic for **Type** and **Account Group** requires additional configuration:

1. **Lead Conversion Flow:** Use a "Before-Save" Flow on the Account object that triggers when the `IsConverted` flag from the Lead is true. This ensures that values like "Dealer Simple" or "Sold To" are assigned accurately based on the source Lead's Record Type.

2. **Data Integrity:** Since these fields are essential for the **SAP Customer Master**, a validation rule should ensure that required fields (Sales Org, Fiscal Address, etc.) are populated on the Lead *before* the user is allowed to convert it.

Architectural Insight: The SAP Lifecycle

By setting the initial **Status** to "Prospect" and the **Account Group** to "Sold To" or "Dealer Simple," we prepare the record for its first integration payload. The transition to "Pending" serves as a technical signal that the record is currently in the integration queue, preventing users from making further changes until SAP returns the official Customer Code.
